Fakultät für Informatik

TU Dortmund

- Application Fields of ANNs
 - Classification
 - Prediction
 - Function Approximation
- Recurrent MLP
 - Elman Nets
 - Jordan Nets
- Radial Basis Function Nets (RBF Nets)
 - Model
 - Training

Classification

given: set of training patterns (input / output) output = label (e.g. class A, class B, ...) $\widetilde{\boldsymbol{x}} : \quad \widetilde{\boldsymbol{u}} :$

phase I:

train network

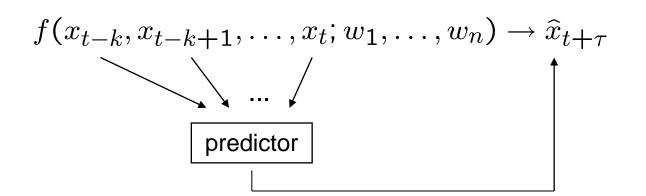

phase II:

apply network to unkown inputs for classification

Prediction of Time Series

time series $x_1, x_2, x_3, ...$ (e.g. temperatures, exchange rates, ...)

task: given a subset of historical data, predict the future

training patterns:

historical data where true output is known;

error per pattern = $(\hat{x}_{t+\tau} - x_{t+\tau})^2$

phase I:

train network

phase II:

apply network to historical inputs for predicting <u>unkown</u> outputs

Prediction of Time Series: **Example for Creating Training Data**

given: time series 10.5, 3.4, 5.6, 2.4, 5.9, 8.4, 3.9, 4.4, 1.7

time window: k=3

(10.5, 3.4, 5.6) 2.4 first input / output pair

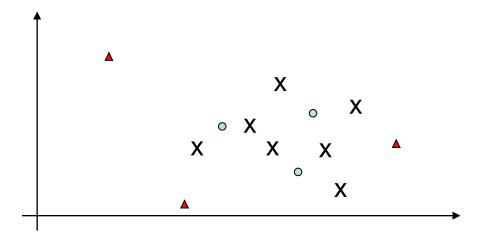

known known input output

further input / output pairs: (3.4, 5.6, 2.4) 5.9 (5.6, 2.4, 5.9) 8.4 (2.4, 5.9, 8.4) 3.9 (5.9, 8.4, 3.9) 4.4 (8.4, 3.9, 4.4)

Function Approximation (the general case)

task: given training patterns (input / output), approximate unkown function

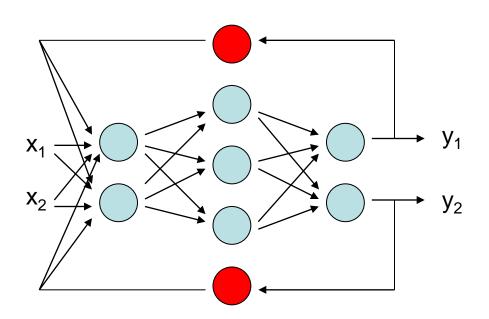

- → should give outputs close to true unknown function for arbitrary inputs
- values between training patterns are interpolated
- values outside convex hull of training patterns are extrapolated

- x: input training pattern
- input pattern where output to be interpolated
- ▲ : input pattern where output to be extrapolated

Jordan nets (1986)

context neuron:
 reads output from some neuron at step t and feeds value into net at step t+1

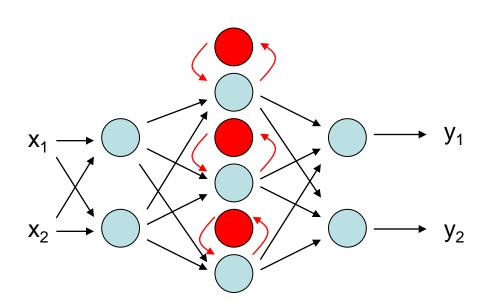

Jordan net =

MLP + context neuron for each output, context neurons fully connected to input layer

Elman nets (1990)

Elman net =

MLP + context neuron for each hidden layer neuron's output of MLP, context neurons fully connected to emitting MLP layer

Training?

- ⇒ unfolding in time ("loop unrolling")
- identical MLPs serially connected (finitely often)
- results in a large MLP with many hidden (inner) layers
- backpropagation may take a long time
- but reasonable if most recent past more important than layers far away

Why using backpropagation?

⇒ use *Evolutionary Algorithms* directly on recurrent MLP!

Lecture 03

Definition:

A function $\phi: \mathbb{R}^n \to \mathbb{R}$ is termed **radial basis function**

iff
$$\exists \varphi : \mathbb{R} \to \mathbb{R} : \forall \mathsf{x} \in \mathbb{R}^n : \phi(\mathsf{x}; \mathsf{c}) = \varphi(\|\mathsf{x} - \mathsf{c}\|). \quad \Box$$

Definition:

RBF local iff

$$\varphi(r) \to 0 \text{ as } r \to \infty$$

typically, || x || denotes Euclidean norm of vector x

examples:

$$\varphi(r) = \exp\left(-\frac{r^2}{\sigma^2}\right)$$

Gaussian

unbounded

$$\varphi(r) = \frac{3}{4} (1 - r^2) \cdot 1_{\{r \le 1\}}$$

Epanechnikov

bounded

$$\varphi(r$$

 $\varphi(r) = \frac{\pi}{4} \cos\left(\frac{\pi}{2}r\right) \cdot 1_{\{r \le 1\}}$

Cosine

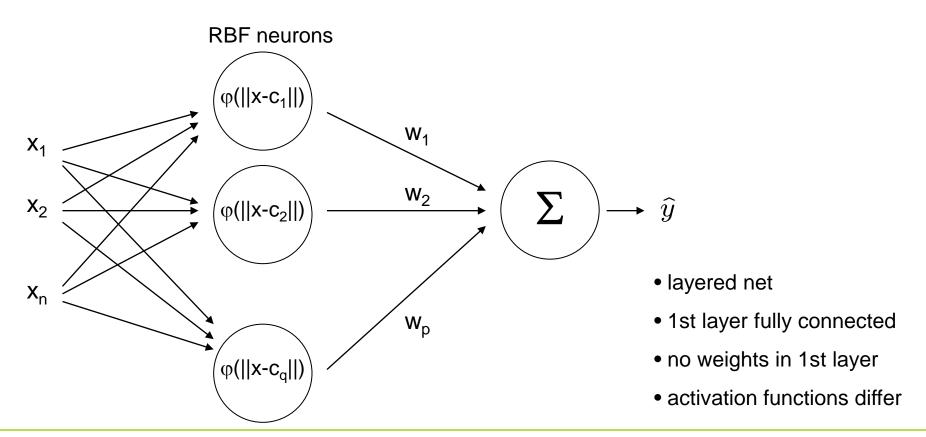

bounded

local

Definition:

A function f: $\mathbb{R}^n \to \mathbb{R}$ is termed radial basis function net (RBF net)

iff
$$f(x) = w_1 \varphi(||x - c_1||) + w_2 \varphi(||x - c_2||) + ... + w_p \varphi(||x - c_q||)$$

given: N training patterns (x_i, y_i) and q RBF neurons

find : weights $w_1, ..., w_q$ with minimal error

solution:

we know that $f(x_i) = y_i$ for i = 1, ..., N and therefore we insist that

$$\sum_{k=1}^{q} w_k \cdot \varphi(||x_i - c_k||) = y_i$$

$$\downarrow \qquad \qquad \downarrow$$

$$\downarrow \qquad \qquad \downarrow$$

$$\text{unknown known value known value}$$

$$\Rightarrow \sum_{k=1}^q w_k \cdot p_{ik} = y_i \qquad \Rightarrow \text{N linear equations with q unknowns}$$

Lecture 03

in matrix form:
$$P w = y$$

with
$$P = (p_{ik})$$
 and $P: N \times q$, $y: N \times 1$, $w: q \times 1$,

case
$$N = q$$
:

$$W = P^{-1} y$$

$$W = P^+ y$$

where P+ is Moore-Penrose pseudo inverse

$$P w = y$$

$$P'Pw=P'y$$

$$(P'P)^{-1} P'P w = (P'P)^{-1} P' y$$
unit matrix P+

- existence of (P'P)⁻¹ ?
- numerical stability?

Lecture 03

Tikhonov Regularization (1963)

idea:

$$\overline{\text{choose}} \ (P'P + h I_q)^{-1} \text{ instead of } (P'P)^{-1}$$

 $(h > 0, I_q \text{ is } q\text{-dim. unit matrix})$

excursion to linear algebra:

Def : matrix A positive semidefinite (p.s.d) iff $\forall x \in \mathbb{R}^n : x'Ax \geq 0$

Def : matrix A positive definite (p.d.) iff $\forall x \in \mathbb{R}^n \setminus \{0\} : x'Ax > 0$

Thm: matrix $A: n \times n$ regular \Leftrightarrow rank $(A) = n \Leftrightarrow A^{-1}$ exists $\Leftarrow A$ is p.d.

Lemma : a, b > 0, $A, B : n \times n$, A p.d. and B p.s.d. $\Rightarrow a \cdot A + b \cdot B$ p.d.

Proof :
$$\forall x \in \mathbb{R}^n \setminus \{0\} : x'(a \cdot A + b \cdot B)x = \underbrace{a \cdot \underline{x'Ax} + \underline{b} \cdot \underline{x'Bx}}_{} > 0$$

Lemma : $P: n \times q \Rightarrow P'P$ p.s.d.

Proof : $\forall x \in \mathbb{R}^n : x'(P'P)x = (x'P') \cdot (Px) = (Px)'(Px) = \|Px\|_2^2 \ge 0$ q.e.d.

q.e.d.

Tikhonov Regularization (1963)

$$\Rightarrow (P'P + h I_q)$$
 is p.d. $\Rightarrow (P'P + h I_q)^{-1}$ exists

question: how to justify this particular choice?

$$||Pw - y||^2 + h \cdot ||w||^2 \to \min_w!$$

interpretation: minimize TSSE and prefer solutions with small values!

$$\frac{d}{dw}[(Pw - y)'(Pw - y) + h \cdot w'w] =$$

$$\frac{d}{dw}[(w'P'Pw - w'P'y - y'Pw + y'y + h \cdot w'w] =$$

$$2P'Pw - 2P'y + 2h w = 2(P'P + h I_q) w - 2P'y \stackrel{!}{=} 0$$

$$\Rightarrow w^* = (P'P + h I_q)^{-1} P' y$$

$$\frac{d}{dw}[2(P'P+hI_q)x-2P'y]=2(P'P+hI_q)$$
 is p.d. \Rightarrow minimum

Tikhonov Regularization (1963)

question: how to find appropriate h > 0 in $(P'P + h I_q)$?

let PERF(h;T) with $\text{PERF}:\mathbb{R}^+\to\mathbb{R}^+$ measure the performance of RBF net for positive h and given training set T

find
$$h^*$$
 such that $\operatorname{PERF}(h^*;T) = \max\{\operatorname{PERF}(h;T) : h \in \mathbb{R}^+\}$

- → several approaches in use
- → here: grid search and crossvalidation

```
(1) choose n \in \mathbb{N} and h_1, \ldots, h_n \in (0, H] \subset \mathbb{R}^+; set p^* = 0
```

- (2) for i=1 to n
- $(3) p_i = PERF(h_i; T)$
- (4) if $p_i>p^*$
- $(5) p^* = p_i; k = i;$
- (6) endif
- (7) endfor
- (8) return h_k

grid search

Lecture 03

Crossvalidation

choose $k \in \mathbb{N}$ with k < |T|let T_1, \ldots, T_k be partition of training set T

$$T_1 \cup \ldots \cup T_k = T$$

 $T_i \cap T_j = \emptyset \text{ for } i \neq j$

- PERF(h;T) =
- (1) set err = 0
- (2) for i = 1 to k
- (3) build matrix P and vector y from $T \setminus T_i$
- (4) get weights $w = (P'P + hI)^{-1}P'y$
- (5) build matrix P and vector y from T_i
- (6) get error e = (Pw y)'(Pw y)
- $(7) \quad err = err + e$
- (8) endfor
- (9) return 1/err

complexity (naive)

$$W = (P'P)^{-1} P' y$$

P'P: N² q

inversion: q³

P'y: qN

multiplication: q²

O(N² q) elementary operations

remark: if N large then inaccuracies for P'P likely

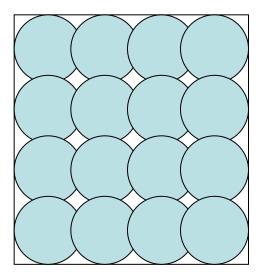

⇒ first analytic solution, then gradient descent starting from this solution

requires
differentiable
basis functions!

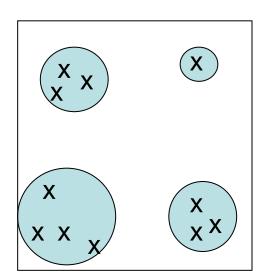

so far: tacitly assumed that RBF neurons are given

 \Rightarrow center c_k and radii σ considered given and known

how to choose c_k and σ ?

uniform covering

if training patterns inhomogenously distributed then first cluster analysis

choose center of basis function from each cluster, use cluster size for setting σ

advantages:

- additional training patterns → only local adjustment of weights
- optimal weights determinable in polynomial time
- regions not supported by RBF net can be identified by zero outputs
 (if output close to zero, verify that output of each basis function is close to zero)

disadvantages:

- number of neurons increases exponentially with input dimension
- unable to extrapolate (since there are no centers and RBFs are local)
